

WHAT IS APPGUARD?

AppGuard is a protection software package that is installed on laptops, desktops and servers to defeat all forms of malicious software attacks. It is completely different from traditional cyber security solutions – it is not antivirus, it does not detect and respond, it simply STOPS all attacks by blocking and isolating them before they can do any harm.

Used worldwide, AppGuard has never been breached in its 20 year existence, giving complete reassurance that their data is secure and protected from cyber criminals.

AppGuard is a revolutionary technology that is a complete cyber protection against all known and unknown Malware threats. Working independently from anti virus software, this state-of-the-art defence controls unauthorised applications, stops the installation of unauthorised software, reduces the need for so many security software patches and provides vital intelligence on the origin of blocked attacks.

Tested, compared, delivered and supported throughout the UK 24/7 365 by Cyber Security Associates Limited, a Managed Security Service Provider, we've proudly been appointed to distribute, deploy, manage and support all installations.

WHY APPGUARD?

Existing Cyber Security defences and products are not effective against sophisticated threats and attacks; therefore, preventing the attack from ever happening is the path to true security. The latest technology and tools currently rely on known threats and attack methods to stop further infections and attacks, which means there will always be a 'patient zero'. AppGuard works differently and throws out the rulebook of traditional defences by blocking and isolating attacks before they happen.

AppGuard provides a full protect capability with easily accessible dashboards with a fast and simple automated deployment that can be managed by either an organisation or the CSA MSSP. AppGuard is available for both Home and Business users, ensuring everyone is protected no matter what IT they are using.

WHAT DOES APPGUARD PROVIDE?

- AppGuard prevents breaches at the endpoint by blocking applications from performing unrecognised processes while allowing harmless and authorised processes to continue.
- Requires no updates or an Internet connection to operate, allowing deployment on non-connected IT and other infrastructures.
- Allows an organisation to lock-down usage of external devices (USBs, DVDs) and only allow authorised devices to be used.
- Prevents the unauthorised installation of software and will only allow installations approved by the organisation.
- It has a very small footprint using a small amount of memory to operate and has no endpoint latency, ensuring it remains lightweight.
- Stops all variants of Malware and Ransomware and can be deployed after an attack to stop any infections from spreading.
- Offers multiple deployment and support options ranging from fully managed to co-managed to self-managed for Home and Business users.
